

Title: Wave Management help for a hardstuck ADC silver player

Score:

--- POST CONTENT ---

Hello, I'm a hard stuck silver that has hit gold in previous seasons, that's enough flexing. I am able to consistently get around 7-8cspm in lane and around 8cs/m late/mid and have gotten 10cspm previously. I'm not the perfect CSer. Anyway, what I'm asking is, before I recall for a good timer should I fast push or freeze the wave in front of my turret. I feel as though freezing would deny more CS and keep the wave in a preferable state, but fast pushing will cause it to slow push into me anyway so I can set up another freeze. What is the best option to either gain a gold advantage or snowball one.

If you're still in silver after getting 8+ cs/m consistently, CS and wave management are not your problems. Anyways, before recalling you should almost always shove the wave

Getting high CS numbers is less about being good at CSing and more about making good macro movements.

This ties directly wave management, as you should know what a wave is going to do in order to inform your decision.

There are three main wave management techniques and using them at the right time is key to good macro.

1. Hard shove: this is the weakest technique. I see lots of comments recommending this, mostly suggesting to do so before a buy. This is a good rule but a bit simple of an explanation.

You should only hard shove if crashing the wave into the enemy turret is beneficial to you.

If you hard shove a wave of 6 minions, the enemy can clear it before the next wave arrives and you either have to hard shove into them again or lose minions when you base

2. Freezing: the second strongest technique. This revolves around a concept known as the "even minion rule". Simply put, a wave will push towards the enemy if there are even minions on each side but it's closer to an ally turret. This is because the minions from the next wave arrive earlier on the ally side and will help push the wave.

Keeping the numbers in your favor , with enough enemy minions to kill your wave before it moves , will freeze your wave.

You can use this to farm safe near your turret and make the enemy over extend

3. Slow pushing , the final and most potent technique.

As mentioned with hard shoving , small waves pushed into enemy turret do not give you a lot of time to make a play. By only last hitting minions(and many other ways? watch a vid if you haven?t), You can achieve a slow push

The more minions you build up before crashing into enemy turret. The more time you have to make

a play elsewhere , whether that's basing to spend gold or roaming for a kill/objective

???

If I were you I would master the slow push, learn to see what waves are doing on the minimap so you know where to go and farm mid game after

Laning phase.

[Comment 3 | Score: 3]

If you can safely, always push the wave into your opponent tower before backing. That way they lose CS to tower and you get a nice, safe wave when you return.

[Comment 4 | Score: 2]

Biggest things besides mini-map awareness, making yourself as hard to gank as possible, playing safe into lanes you don't win against, and just learning how to play safe/avoiding poor engages will be big things to watch for.

There are a lot of little things that are impossible to point out unless someone watches your actual gameplay, so hopefully that person who added you will help out.

Bot lane also has the questionable joy of having to rely on others so you are forced to adapt to their skill each time. I haven't played ranked in a long time, but when I did I pretty easily hit plat 1, and uh, it doesn't really get better. So good luck lol?

[Comment 5 | Score: 2]

If you can shove the wave in all the way to tower let's say after a clean doublekill on the enemy

botlane, that is the best you can do.

&#x200B;

If you just kill their adc and you are too low to push the wave in with the enemy support threatening to freeze the wave for his adc, sometimes leaving the lane to freeze is the better choice.

&#x200B;

All depends on the situation, really.
