

Title: Does wave management work differently on bot or matter less?

Score:

--- POST CONTENT ---

So I main top and secondarily supp. Currently low plat and Ive noticed that the toplaners in my elo usually have a good grasp of wave management, they freeze if they can deny minions and push the wave out when they want to back. When Im playing supp however, most ADCs seem to never wanna freeze even if we got all the pressure and can zone the enemies out of the wave and neither freeze when the enemy is currently off the lane and we can make them loose some waves. Most either effectively slowpush or if we wanna back they shove (which Id do too on top so I help them then). However, even when I got to lane before my ADC and set up a freeze, most will push it out immediately. They handle minions completely differently than I would on top.

Now, is this because as an ADC you want different things from the wave? Or does wave management matter less on bot than on top so ADCs dont bother as much as toplaners of similiar rank?

Wave management applies to all roles, but in botlane you have to attempt to be on the same page as your laner, and also deal with pressure from two other opponents

Just a lot more variables to consider so there is less effective wave management in general

[Comment 2 | Score: 111]

It's just as powerful and important in the bot lane as in top lane. I don't know exactly why, but it's just my guess on why overall bot laners are way worse in wave manipulation is because top laners get punished way harder for messing up their waves. Also, guys on the island are way more bloodthirsty than bot laners.

[Comment 3 | Score: 23]

It works the same but is potentially way harder because there's basically always two opponents making it harder to zone then off and if the opposing support is ranged it can become pretty risky as they can help break the freeze without extending as far forward as melee tops have to.

[Comment 4 | Score: 55]

I wouldn't say it's less important, just harder to take full advantage of it.

Killing the enemy top let's you shove the wave. This denies the enemy gold, xp, and may even get you a plate or two. In the bot lane, a single kill still leaves the ADC or support to hoover up the minions and keep you from free hitting the tower.

Freezing is harder. Both players need to be on the same page. And breaking the freeze is easier because fighting with minion advantage is more beneficial when everyone is a squishy bot lane as opposed to a beefy top.

[Comment 5 | Score: 36]

Having supports going for poke or using pauldron inherently results in messier waves as minions catch strays on both sides. There's 4, and often more people down there getting goofy, and I find it's less wave management and more of adapting to the wave state that's being influenced by 3x as many external sources as a 1v1. Can't even fathom how many times a support has whiffed a

skill into the minion wave and suddenly they're low enough to get one shot by tower and you have to enter damage control or just lose those minions. And trying to tank minions to hold a wave is a bit less viable for an ADC or many supports, or they don't even consider it.

So to answer the title question, a bit of both.
